Phenomenological studies on searching for long-lived particles with displaced vertices and jets at the LHC

## Zeren Simon Wang 王泽人 (HFUT)

<u>JHEP 07 (2024) 209</u>: K. Cheung, F.-T. Chung, G. Cottin, **ZSW** <u>Phys. Rev. D 110, 055033</u>: **ZSW** <u>2501.09065</u>: R. Beltrán, G. Cottin, J. Günther, M. Hirsch, A. Titov, **ZSW** 

University of Science and Technology of China, Hefei, China May 9<sup>th</sup>, 2025

## Outline

2 Recast and reinterpret an ATLAS search

ъ.

**N A B N** 

## Motivation

- SM: basis of modern understanding of particle physics
- Successful predictions: W, Z, h, g, c, t,  $\tau$ , ...
- Excellent performance in experimental tests (e.g. EW sector)
- Issues: neutrino masses, baryon asymmetry, DM, non-unification of gauge couplings, strong CP problem, charge quantization...
- Hint at GUT & NP  $\Rightarrow$  the hierarchy problem
- NP models including SUSY predict new heavy fields
- No new fundamental particles found yet at the LHC
- More stringent limits placed on NP models, e.g.  $m_{ ilde{q}, ilde{g}}\gtrsim 1$  TeV
- LHC focus: promptly decaying NP particles

## LLPs in the SM

• LLPs: produced, travel a macroscopic distance, and then decay  $\rightarrow$  Displaced objects

LLPs in the SM, **B. Shuve's talk** 

- Causes of the long lifetime:
  - Feeble couplings
  - Heavy mediators

Similarly applicable to BSM particles

## $\ensuremath{\mathsf{LLPs}}$ in the BSM theories

Examples:

- Portal physics:  $\nu_4$ ,  $\gamma'$ , s, and a
- RPV/compressed SUSY
- Mirror glueballs
- .
- See <u>1903.04497</u> for a review

## Motivation:

- Non-vanishing active-neutrino masses
- Dark matter
- ...

⇒ Can we search for LLPs at colliders e.g. at the LHC? Yes!

1.5

## Part I: Recast and reinterpret an ATLAS search for DVs and jets

Quark flavor violation and axion-like particles from top-quark decays at the LHC, JHEP 07 (2024) 209; K. Cheung, F.-T. Chung, G. Cottin, **ZSW** 

Constraining long-lived particles from Higgs boson decays at the LHC with displaced vertices and jets, Phys. Rev. D 110, 055033; **ZSW** 

## Recast & Reinterpretation

- Experimentalists have performed multiple (LLP) searches
- These reported searches constrained a limited class of models only
- How to obtain their bounds on *other* models predicting *similar/identical signatures*?

## Pheno approach:

- **Q** Recast: follow event selections of experimental searches step by step
- **Validation**: reproduce the published cutflow and/or exclusion limits
- Reinterpretation: apply the same analysis on your favorite NP model to derive the corresponding limits

## LHC LLP searches

LLP signatures at colliders and the exponential decay distribution (<u>H. Russell's talk</u>)

- Disappearing track: <u>2309.16823</u>, <u>2201.02472</u>, ...
- DVs and missing transverse momentum: <u>2402.15804</u>, <u>1710.04901</u>, ...
- DV and a lepton: <u>2003.11956</u>, ...
- Displaced leptons: <u>2011.07812</u>, <u>2110.04809</u>, ...
- Delayed or non-pointing photons: <u>2209.01029</u>, ...
- DVs and jets: <u>2301.13866</u>

ヘロマ 不留 マイドマ キャン ひょう

## The ATLAS DV+jets search

<u>2301.13866</u>: 13 TeV, 139 fb<sup>-1</sup>

- Signal regions: High- $p_T$  jet and Trackless jet
- Long-lived electroweakinos with RPV  $\lambda'' \bar{U} \bar{D} \bar{D}$  operators:  $\tilde{\chi} \rightarrow qqq$ 
  - Strong channel:  $pp \rightarrow \tilde{g}\tilde{g}$  with  $\tilde{g} \stackrel{\text{prompt}}{\rightarrow} \tilde{\chi}_1^0 qq$
  - EW channel:  $pp \to \tilde{\chi}\tilde{\chi}$  with  $\tilde{\chi} = \tilde{\chi}_1^0, \tilde{\chi}_2^0, \tilde{\chi}_1^{\pm}$
- Require large jet-p<sub>T</sub> at the truth-level (differing between the two SRs)
- Requires at least one DV of quality
- Delicate requirements such as multi-jet trigger and material veto

SR	Observed	Expected	$S_{ m obs}^{95}$	$S_{ m exp}^{95}$	$\langle \sigma_{vis} \rangle_{obs}^{95}$ [fb]
High- <i>pT</i> -jet SR	1	$0.46^{+0.27}_{-0.30}$	3.8	$3.1^{+1.0}_{-0.1}$	0.027
Trackless-jet SR	0	$0.83^{+0.51}_{-0.53}$	3.0	$3.4^{+1.3}_{-0.3}$	0.022

## Recast procedure of the ATLAS DV+jets search

- Follow ATLAS recast instructions for this search; see also HEPData
- Event generation:
  - $\bullet$  Generate signal events in <code>MadGraph5</code> with the SUSY SLHA spectrum files provided by <code>ATLAS</code>
  - CKKW-L jet-merging with up to 2 additional jets in the hard processes
  - Truth jets reconstructed with FastJet; using particles including those from the LLP decays
- Event selections:
  - Event- & Vertex-level acceptances:  $\mathcal{A}_{event}$ ,  $\mathcal{A}_{vertex}$
  - Event- & Vertex-level efficiencies:  $\epsilon_{\text{event}}$ ,  $\epsilon_{\text{vertex}}$
- Apply parameterized efficiencies to account for delicate requirements; Provided by ATLAS
- Final cutflow efficiency:

$$\epsilon = \mathcal{A}_{\mathsf{event}} \cdot \epsilon_{\mathsf{event}} \cdot \left( 1 - \prod_{\mathsf{vertex}} (1 - \mathcal{A}_{\mathsf{vertex}} \cdot \epsilon_{\mathsf{vertex}}) \right)$$

くらく エード・トリー シック

## Event- and vertex-level acceptances

•  $\mathcal{A}_{event}$ :

SR	High- <i>p<sub>T</sub></i> jet	Trackless jet
Jet selection	$n_{jet}^{250} \ge 4 \text{ or } n_{jet}^{195} \ge 5$ or $n_{jet}^{116} \ge 6 \text{ or } n_{jet}^{90} \ge 7$	$ \begin{array}{c} n_{jet}^{137} \geq 4 \text{ or } n_{jet}^{101} \geq 5 \\ \text{or } n_{jet}^{83} \geq 6 \text{ or } n_{jet}^{55} \geq 7, \\ n_{displaced jet}^{70} \geq 1 \text{ or } n_{displaced jet}^{50} \geq 2 \end{array} $

"displaced jet" defined by matching jets with LLP decay products

•  $\mathcal{A}_{vertex}$ : at least one vertex should pass a list of vertex requirements:

- (1) 4 mm  $< R_{xy} < 300$  mm and |z| < 300 mm
- 2 At least one track should satisfy  $d_0 > 2 \text{ mm}$
- The displaced vertex should have at least 5 decay products of a massive particle satisfying the following requirements:

() It should be a track with a boosted transverse decay length > 520 mm

2 Its  $p_T$  and charge q should obey the relation  $p_T/|q|>1$  GeV

 m<sub>DV</sub> > 10 GeV; truth vertex constructed with the decay products passing the requirements above, for which the mass of each decay product is assumed to be m<sub>π±</sub>

▲母 ▶ ▲ ヨ ▶ ▲ ヨ ▶ ヨ ■ ● ● ●

## Parameterized efficiencies

- Parameterized efficiencies provided by the ATLAS collaboration at both event- and vertex-levels that account for quality requirements such as multi-jet trigger, jet filter, and material effects that are difficult to simulate
- Applied to truth-level objects!

 $\epsilon_{\text{event}}$ : functions of the truth-jet scalar  $p_T$  sum and  $R_{xy}$  of the furthest LLP decay  $\epsilon_{vertex}$ : for reconstructing the DVs; functions of  $R_{xy}$ ,  $m_{DV}$ , and the LLP decay-product multiplicity  $n_{trk}$ 

## Validation results:

High- $p_T$ -jet SR acceptance and final cutflow efficiency

- Strong channel,  $\tilde{\chi}_1^0$  decaying to light-flavor quarks

## Discussions on the validation

- Generally excellent validation results with the acceptance requirements only  $\Rightarrow$  we should have selected the correct set of events from the whole event samples
- Inputs of the event-level and vertex-level efficiencies determine also the acceptance-level cutflows
- Cannot find issues within coding itself either
- Cannot explain the discrepancies, and urge for further collaboration between the theorists and experimentalists
- Uploaded our code to the public LLP Recasting Repository
- Assign an uncertainty of 50% in numerical studies

くゆ エヨト イヨト ヨヨ ろくつ

## Reinterpretation: axion-like particles

- Axion-like particles (ALPs): pseudoscalar particles; predicted in string compactifications, supersymmetry models, Froggat-Nielsen models of favor, ...
- Do not necessarily solve the strong CP problem in the SM as the QCD axions do
- A rich phenomenology at various terrestrial experiments

## Quark flavor violation

• Consider a scenario with a Lagrangian where the ALPs couple at tree level to quarks only, both diagonally and off-diagonally

$$\mathcal{L}_{a, \text{ eff}} = \frac{\partial^{\mu} a}{2\Lambda} \Big( \sum_{i=1,2,3} \mathbf{g}_{ii} \ \bar{q}_i \gamma_{\mu} \gamma_5 q_i + \sum_{i,j=1,2,3}^{i \neq j} \mathbf{g}_{ij} \ \bar{u}_i \gamma_{\mu} \gamma_5 u_j \Big) \\ + \frac{1}{2} (\partial_{\mu} a) (\partial^{\mu} a) - \frac{1}{2} m_a^2 a^2$$

- g's: real and positive
- Quark-flavor off-diagonal couplings motivated in UV-complete models
- Off-diagonal: focus on t u a and t c a
- Diagonal: all quarks
- Remain agnostic on a UV-completion origin for exactly this particular flavor structure and treat the ALP-quark couplings as independent parameters in this phenomenological work

(日本)

## Signal process

$$pp \xrightarrow{SM} t\bar{t}, (t \to W^+ b, W^+ \to jj), (\bar{t} \to \bar{u}_i a, a \xrightarrow{\text{disp.}} jj), \text{ with } i = 1, 2$$

and its charge-conjugated channel

- jj denotes two jets including the b-quarks
- a: long-lived and decays to jj with a displacement from the IP
- Assume  $g_{ii}$  with i = 1, 2, 3 ('decay couplings') are non-vanishing and universal, and  $g_{31} = g_{13} = g_{32} = g_{23}$  ('production couplings')

$$\Gamma(t \to au_i) = \frac{N_c}{384\pi} \frac{g_{3i}^2}{\Lambda^2} \frac{m_a^2}{m_t} \left( \frac{(m_t^2 - m_{u_i}^2)^2}{m_a^2} - (m_t^2 + m_{u_i}^2) \right) \\ \times \sqrt{\left( 1 - \frac{(m_a + m_{u_i})^2}{m_t^2} \right) \left( 1 - \frac{(m_a - m_{u_i})^2}{m_t^2} \right)}$$

▲□ ▲ □ ▲ ■ ▲ ■ ■ ■ ● ● ●

## ALP decays via diagonal couplings

### • The main channel:

$$\Gamma(\mathbf{a} \to \mathbf{q}_i \bar{\mathbf{q}}_i) = \frac{N_c m_a m_{q_i}^2}{8\pi} \frac{\mathbf{g}_{ii}^2}{\Lambda^2} \sqrt{1 - 4m_{q_i}^2/m_a^2}$$

• Applicable for  $m_a\gtrsim 1$  GeV (perturbative QCD)

#### Other channels:

- $a \rightarrow gg$  via  $g_{ii}$ : Br can be up to about 40% for  $m_a \lesssim 100$  GeV; leads to the same signatures and could only enhance the bounds on the production couplings mildly; ignored for simplicity
- $a \to \gamma \gamma$ : for  $m_a \sim \mathcal{O}(10)$  GeV, suppressed by more than two orders of magnitude; ignored
- $a \rightarrow q_i q_j$  at loop level: suppressed and ignored

(日) (四) (日) (日) (日) (日) (日)

## ALP decays via off-diagonal couplings

•  $g_{3i} \Rightarrow$  3-body or 4-body ALP decays; important if  $g_{3i} \gg g_{jj}$ :

$$a \stackrel{g_{3i}}{\longrightarrow} \bar{u}_i t^* \to \bar{u}_i \, b \, W^{+(*)} \to \bar{u}_i \, b \, (jj \text{ or } l^+ \, \nu), \text{ with } i = 1, 2$$

- *W*-boson off-shell (4-body decays) or on-shell (3-body decays), depending on *m*<sub>a</sub>
- For  $m_a \lesssim m_W + m_b \sim 85$  GeV,  $g_{3i}$ 's can induce ALP 4-body decays which can be the dominant decay modes if the production coupling is larger than the decay coupling by at least around 4 orders of magnitude (checked numerically with MadGraph5)
- Automatic calculation of the decay widths of these 4-body decay modes within MadGraph5 too much time-consuming ⇒ Not including them in our computation and restrict ourselves to the parameter space where such contributions are unimportant
- For  $m_t \gtrsim m_a \gtrsim m_W + m_b$ , the off-diagonal couplings can result in ALP 3-body decays and these modes are included in our computation

## Present bounds on ALP-quark couplings

- Low-energy precision measurements: rare decays of kaons, *D* and *B*-mesons, and  $J/\Psi$ ; relevant only to the ALPs lighter than the *B*-mesons
- Collider searches: dominant bounds for  $m_a \gtrsim 10$  GeV
- We focus on  $m_a \gtrsim 10$  GeV because of  $m_{\rm DV} > 10$  GeV required
- Relevant existing bounds:

Ref.	Method	Couplings bounded	Our finding
JHEP 09 (2023) 063	Recast an ATLAS search	$g_{tt}/\Lambda$	Orders of magnitude weaker than our bounds
Phys.Rev.Lett. 133, 161803	Performed an ATLAS DV search	$g_{3,1}/\Lambda \& g_{3,2}/\Lambda$	1+ order of magnitude weaker than our bounds
JHEP 07 (2022) 122	Recast CMS & ATLAS searches	$g_{3,1}/\Lambda$ & $g_{3,2}/\Lambda$	We recast&reinterpret the searches

- <u>CMS search</u>: top + jets
   <u>ATLAS search</u>: top + MET
- Following JHEP 07 (2022) 122 for recasting these searches
- Not giving detail here

<<p>◆日本

## Simulation & Computation

- UFO model of the ALP: FeynRules
- Signal-event generation: MadGraph5,  $10^6$  events simulated at each parameter point in a grid scan over prod. coup., decay coup., and  $m_a$
- $\Gamma_a$ : auto-computed within MadGraph5
- Showering, hadronization, and completing the truth-level decay chains of the produced particles: Pythia8
- Estimate of  $\epsilon$ : our recasting code

$$N_{S} = 2 \cdot \mathcal{L} \cdot \sigma(pp \to t\bar{t})_{SM} \cdot \mathcal{B}(t \to W^{+}b) \cdot \mathcal{B}(W^{+} \to jj)$$
$$\cdot \mathcal{B}(\bar{t} \to ja) \cdot \mathcal{B}(a \to jj) \cdot \epsilon$$

- $\mathcal{L}$ : integrated luminosity j = u, d, s, c, b
- $\mathcal{B}(t \to W^+ b) = 99.7\%$   $\mathcal{B}(W^+ \to ij) = 67.41\%$
- $\sigma(pp \rightarrow t\bar{t})_{SM} = 833.9$  pb computed at NNLO+NNLL with the Top++2.0 program for  $\sqrt{s} = 13$  TeV

## Reinterpretation results -g vs. g

- Assume the same  $S_{obs}^{95}$  values for both 139 fb<sup>-1</sup> and 3000 fb<sup>-1</sup>

## Reinterpretation results -g vs. $m_a$

Searching for LLPs w/ DV & jets at the LHC

-

Long-lived scalars from Higgs-boson decays at the LHC

- New scalars: models of singlet-scalar-extended SM, neutral-naturalness, 2HDM, SUSY, ...
- Benchmark scenarios:  $h \rightarrow \phi \phi$ ,  $\Phi \rightarrow ss$
- Simulation:
  - Monte-Carlo simulation with Pythia8
  - Scan over mass and lifetime of the LLPs
  - Use the module HiggsSM:gg2H for simulating the gluon-fusion process with  $\sqrt{s}=13~{\rm TeV}$

$$N_{S} = \sigma(\mathsf{LLP}) \cdot \mathcal{L} \cdot \epsilon \cdot (\mathsf{Br}(\mathsf{sig.}))^{2}$$

- $\epsilon$ : the final cutflow efficiencies of the ATLAS DV+jets search
- Br(sig.): signature final states
- Power of 2: *both* LLPs  $\xrightarrow{decay}$  the specified signature final states

<<p>◆日本

## $h \rightarrow \phi \phi$

• A light singlet scalar from SM-like Higgs-boson decays

• mass range: 
$$m_{\phi} \sim [10 \text{ GeV}, 62 \text{ GeV}]$$

- 10 GeV:  $m_{\rm DV} > 10$  GeV
- 62 GeV: phase-space requirement

• Signal process: 
$$pp \xrightarrow{g.t.} h \to \phi\phi, (\phi \to b\bar{b}, \phi \to b\bar{b})$$

•  ${\rm Br}(\phi 
ightarrow b ar{b})$  computed with HDECAY

• 
$$\sigma(pp \xrightarrow{\text{g.f.}} h) = 48.5 \text{ pb at } \sqrt{s} = 13 \text{ TeV}$$

## Reinterpretation results

## $\Phi \to \textit{ss}$

- A heavy Higgs boson and a long-lived light scalar
- Benchmark scenarios following ATLAS searches:
  - $\frac{1911.12575}{\bullet (m_{\Phi}, m_s)} = (600 \text{ GeV}, 150 \text{ GeV})$ •  $(m_{\Phi}, m_s) = (1000 \text{ GeV}, 275 \text{ GeV})$ 
    - $(m_{\Phi}, m_s) = (1000 \text{ GeV}, 400 \text{ GeV})$

Signal process:  $pp \xrightarrow{g.f.} \Phi \to ss, (s \to x\bar{x}, s \to x\bar{x})$ , with  $x = b, c, \tau$ 

• 
$$Br(s \to b\bar{b}) = 85\%, Br(s \to c\bar{c}) = 5\%, Br(s \to \tau\bar{\tau}) = 8\%$$

(日本)

# Part II: Propose an LHC search for DVs and jets

Heavy neutral leptons and top quarks in effective field theory, <u>2501.09065</u>; R. Beltrán, G. Cottin, J. Günther, M. Hirsch, A. Titov, **ZSW** 

JHEP accepted

## An additional theoretical scenario

- N<sub>R</sub>SMEFT
- Long-lived HNLs and d = 6 operators with top quarks
- HNLs produced from
  - pp collisions in association with a single top
  - On-standard decays of top quarks
- Experiments and Signature:
  - ATLAS; DV+jets
  - LHC far detectors; DV
- Motivations: non-zero  $m_{\nu}$ , dark matter, baryon asymmetry, ...

## *N<sub>R</sub>*SMEFT

- Minimal scenario:  $m_N$  and  $|V|^2$
- UV-completions beyond the SM: Z', U(1)<sub>B-L</sub>, leptoquarks, ...
- No new resonances at the LHC  $\Rightarrow$  Effective Field Theory
- Separation of scales:  $m_N \lesssim v$  and  $\Lambda \gg v$ ; v, Higgs VEV
- *N<sub>R</sub>*SMEFT: EFT that describes the SM with additional light fermionic singlets
- Multiple pheno studies using N<sub>R</sub>SMEFT exist
- We focus on operators with top quarks
- Long-lived HNL⇒ displaced signals in the LHC main detectors or far detectors
- Pair- $N_R$  and Single- $N_R$  operators

## Model scenario

- $\mathcal{L}_{Yuk} = Y_{\ell}^{\nu} \overline{L_{\ell}} \tilde{H} N_R + h.c. \Rightarrow \nu N \text{ mixing } V_{\ell N}$  after EWSB
- Assume only one N kinematically relevant
- Assume a Dirac HNL
- 1<sup>st</sup>-gen leptons, 1<sup>st</sup>- and 3<sup>rd</sup>-gen quarks
- $V_{\ell N}$  treated as a free parameter
- Focus on LNC and BNC 4-fermion operators
- We do not use second-generation quark indices

## EFT operators

## HNL decays

- Pair- $N_R$  operators: the HNLs decay essentially only via  $V_{\ell N}$
- Single- $N_R$  operators: induce HNL decays
  - All induce HNL 5-body decays via an off-shell t and an off-shell W-boson; can become 4-body or 3-body decays if m<sub>N</sub> large enough
  - Operators containing two terms, one of which does not involve the top quark, trigger 3-body decays (*m<sub>N</sub>* assumed to be heavy enough to ensure on-shell *b*-quark): *O*<sup>31</sup><sub>LNQd</sub>, *O*<sup>33</sup><sub>LNQd</sub>, *O*<sup>13</sup><sub>LdQN</sub>, *O*<sup>33</sup><sub>LdQN</sub>, and *O*<sup>31</sup><sub>QuNL</sub>
  - At the one-loop level, the operators leading to 5-body tree-level decays will also trigger 3-body decays:

One-loop diagrams (in the unitary gauge) for the 3-body decay  $N \to \nu bd$  by the operator  $\mathcal{O}_{QuNL}^{13}$ 

- ▲母 ▶ ▲目 ▶ ▲目 ▲ ● ▲ ● ●

## Benchmark scenarios

Operator	Dominant production	Dominant decays
$\mathcal{O}_{uN}^{13}$	$pp  ightarrow tNar{N}$	$V_{\ell N}$
${\cal O}_{{\it QuNL}}^{13}$	$pp  ightarrow tear{N}, pp  ightarrow t uar{N}$	one-loop 3-body and $V_{\ell N}$
$\mathcal{O}_{duNe}^{13}$	pp $ ightarrow tear{N}$	$V_{\ell N}$ for $m_N < m_W$ 4-body (3-body) for $m_N > m_W (m_t)$
${\cal O}_{duNe}^{33}$	top-quark decays	both op. and $V_{\ell N}$

Always turn on a single effective operator structure, together with the standard  $V_{\ell N}$ 

## ATLAS search

- Signature: a DV from the HNL decay, with jets from top-quark or HNL decays
- The ATLAS DV+jets search fails because of its too strong thresholds on jets' p<sub>T</sub>
- Propose a new search strategy with optimal jet cuts and the optional requirement of a *b*-jet:
  - jet- $p_T$  thresholds from a past 8-TeV ATLAS search for DVs
  - DV selections from the recent 13-TeV ATLAS search for DV+jets
- Event generation:
  - FeynRules: UFO model
  - MadGraph5: HNL production processes
  - Scan over  $|V_{e\!N}|^2$  and  $m_N$ , keeping  $c_{\mathcal{O}}^{ij}/\Lambda^2$  constant
  - MadSpin: forcing the HNLs to decay into ejj and  $\nu jj$  via mixing and channels with  $\geq 2$  jets via operators
  - Pythia8: showering, hadronization, and event selections
  - Implemented a toy-detector module in Pythia to reconstruct truth-level jets with FastJet
  - Detector response for jet- $p_T$  measurements included

## ATLAS event selections

- Event-level selections:
  - $n_{\text{jet}}^{90} \ge 4$  or  $n_{\text{jet}}^{65} \ge 6$  or  $n_{\text{jet}}^{55} \ge 6$ , following <u>1504.05162</u>
  - Optionally: require iden. of b-jets for discovery potential
- OV-level selections:
  - Follow 2301.13866 and its recast JHEP 07 (2024) 209
  - $\geq 1$  vertex in the event satisfy the following conditions:
    - $4 \text{ mm} < R_{xy} < 300 \text{ mm}$  and |z| < 300 mm
    - At least one track should satisfy d<sub>0</sub> > 2 mm
    - The displaced vertex should have at least 5 decay products of a massive particle satisfying the following requirements:
      - $\bullet~$  It should be a track with a boosted transverse decay length  $>520~{\rm mm}$
      - Its  $p_T$  and charge q should obey the relation  $p_T/|q|>1$  GeV
    - $m_{\rm DV} > 10~{\rm GeV}$
- Apply parameterized vertex-level efficiencies discussed previously (but not event-level efficiencies)

## Computation of $N_S^{\text{ATLAS}}$ and projected sensitivities

$$\begin{split} N_{S}^{\text{ATLAS}} &= \sigma \cdot \mathcal{L} \cdot \left\{ \mathcal{B}_{\text{mix}} \cdot \varepsilon^{\text{mix}} + \mathcal{B}_{\text{op}} \cdot \varepsilon^{\text{op}} \right\} \\ \mathcal{B}_{\text{mix}} &= \mathcal{B}(N \to ejj) + \mathcal{B}(N \to \nu jj) \\ \mathcal{B}_{\text{op}} &= \mathcal{B}(N \to 5\text{-body tree}) + \mathcal{B}(N \to 3\text{-body loop}) \end{split}$$

•  $\mathcal{L} = 3 \text{ ab}^{-1}$ ; j : u, d, c, s, b;  $\varepsilon^{\text{mix/op}}$ : final cutflow efficiencies

• The vertex-level selection criteria designed to suppress all backgrounds

• 95% C.L. exclusion limits: 3 signal events

## Example of effect on sensitivity if varying jet- $p_T$ thresholds

## LHC far detectors

- reproduced from [2410.19561] (C.-T. Lu, X. Wang, X. Wei, Y. Wu)
- With proton-proton collisions at  $\sqrt{s} = 13-14$  TeV
- ATLAS and CMS usually hard to test meson decay products; LHCb can do, but other limitations (int. lumi.)
- "Far detectors" specifically for LLP searches, macroscopic distances from various IPs allowing for shielding and veto; DV reconstruction inside fiducial volume
- ANUBIS, CODEX-b, FACET, FASER and FASER2, MoEDAL-MAPP1 and MAPP2, and MATHUSLA
- Little background, if not background-free

Computation of  $N_S^{\text{FD}}$  and projected sensitivities

- Not simulating HNL decays in this case
- $\langle P[N \text{ decay in f.v.}] \rangle = \frac{1}{k} \sum_{i=1}^{k} P[N^{i} \text{ decay in f.v.}]$ 
  - k: total number of the simulated HNLs for each HNL mass
  - Individual decay prob. determined by the HNL' s boosted decay length and momentum angle besides the geometry and position of the far detectors
- $N_{S}^{\text{FD}} = \sigma \cdot \mathcal{L} \cdot \langle P[N \text{ decay in } f.v.] \rangle \cdot \mathcal{B}(N \to \text{vis.}) \cdot \varepsilon$ 
  - $\mathcal{B}(N \rightarrow \text{vis.})$ : BR of the HNL into visible final states (that can be induced either via mixing or the operator), for which we have only excluded the fully invisible tri-neutrino final states
  - Assume a detection efficiency of  $\varepsilon = 100\%$
- Zero background: 3 signal events for exclusion limits at 95% C.L.
- Sensitivity limits for larger numbers of signal events provided; sensitivities for other acceptance or background levels

## Numerical results – $|V_{eN}|^2$ vs. $m_N$

## Numerical results – $\Lambda$ vs. $m_N$

## Conclusions

- NP might be hidden in LLPs
- (HL-)LHC can search for LLPs
- Recast a recent ATLAS search for DV plus jets and reinterpreted it in terms of ALPs with QFV and BSM particles from Higgs-boson decays
- Proposed a search for HNLs coupled to top quarks in *N<sub>R</sub>*SMEFT, based on past 8-TeV and 13-TeV ATLAS searches for DV and DV+jets
- Studied also LHC far detectors for the latter case

## Thank You! 谢谢!

## Appendix

Searching for LLPs w/ DV & jets at the LHC

## Pre-selections

- Truth jets are reconstructed with FastJet, using anti- $k_t$  algorithm and R = 0.4 from all selected stable particles excluding neutrinos and muons This definition includes particles from the LLP decay
- Jet momentum smearing is applied
- Displaced jets are defined as those among the jets selected above that are matched with the LLPs' decay positions and have  $|\eta|<2.5$ . By calculating  $\Delta R$  between the LLP decay products and the truth jets, we determine that a truth jet stems from the LLP decay if the closest decay products of the LLP has  $\Delta R<0.3$
- For the displaced truth jets, we require that the matched LLPs should decay with a transverse distance from IP smaller than 3870 mm which corresponds to the region of the calorimeter

## Conditions for safely using the parameterized efficiencies

- The event- and vertex-level acceptances combined should exceed 10%;
- Solution For any parameter-space point, if the corresponding signal events have an acceptance of over 90% with the High- $p_T$ -jet SR, the parameterized efficiencies of the Trackless-jet SR should not be used; and
- The LLP proper decay length of less than 3 meters are recommended for models where "jets primarily originate from the decay of LLPs".

## $h \rightarrow NN$

- Long-lived heavy neutral leptons (HNLs) from SM-like h decays
- $U(1)_{B-L}$ , new particles: N, Z', H, ...
- N: Majorana HNLs

$$\Gamma(h \to NN) = \frac{1}{2} \frac{m_N^2}{\tilde{x}^2} \sin^2 \alpha \, \frac{m_h}{8\pi} \left( 1 - \frac{4m_N^2}{m_h^2} \right)^{3/2}$$

- α: scalar-mixing angle
   g'<sub>1</sub>: gauge coupling of U(1)<sub>B-L</sub>
  - $\tilde{x} = m_{Z'}/2g'_1$ : vev of the new scalar H
- Assume only one generation of N kinematically relevant and that N mixes only with v<sub>e</sub>

$$\mathsf{Br}(h \to \mathsf{NN}) = \frac{\Gamma(h \to \mathsf{NN})}{\Gamma(h \to \mathsf{NN}) + \cos^2 \alpha \, \Gamma^h_{\mathsf{SM}}}$$

$$\begin{split} m_N &= 12 - 62 \text{ GeV}, |U_{eN}|^2 = 10^{-12} - 10^{-6}, \\ m_{Z'} &= 6 \text{ TeV}, g_1' = 0.8, \tilde{x} = 3.75 \text{ TeV}, \\ m_H = 450 \text{ GeV}, \sin \alpha = 0.3 \end{split}$$

## $h \rightarrow NN$

Signal process:  $\sigma(pp \xrightarrow{g.f.} h \to NN) = \cos^2 \alpha \cdot \sigma_h^{g.f.} \cdot Br(h \to NN)$ 

- Decay width of the Majorana HNL: 2010.07305
- Signature final state:  $N \rightarrow \nu_e/e + jj$ , j = u, d, c, s, b
- HNL production mediated by  $\alpha$  and  $\tilde{x}$
- HNL decay induced separately by  $|U_{eN}|^2$

## Reinterpretation results

-

## Identification of *b*-jets

## • <u>2501.09065</u>

We treat a jet as a *b*-jet based on the flavor of the truth quark that initiated the jet. From all truth jets in the event with  $p_T > 20$  GeV and  $|\eta| < 2.5$ , we tag a jet as a *b*-jet if a Monte-Carlo truth *b*-quark with  $p_T > 5$  GeV is found within a cone of size  $\Delta R = 0.3$  around the jet direction. We additionally force a flat *b*-jet identification efficiency of 77%

## Experiments at the LHC

- Consider pp collisions at  $\sqrt{s} = 14$  TeV with equal beam energies
- HL-LHC with 3 ab<sup>-1</sup> integrated luminosity
- Various far detectors have different projected integrated luminosities

## MATHUSLA

 MAssive Timing Hodoscope for Ultra Stable neutraL pArticles: a surface detector above the CMS IP: 100 m × 100 m ×25 m [2009.01693]

Extracted from [1810.03617]

$L_d$ (m)	$L_h$ (m)	$L_{v}$ (m)	<i>H</i> (m)	$\phi/2\pi$	$\mathcal{L}$ (fb <sup>-1</sup> )
100	68	60	25	0.22	3000

## ANUBIS

• AN Underground Belayed In-Shaft search experiment: [1909.13022] In one of the service shafts above the ATLAS or CMS IP

•  $d_h = 5 \text{ m}, d_v = 24 \text{ m}, l_h = 18 \text{ m}, l_v = 56 \text{ m}$ •  $\mathcal{L} = 3000 \text{ fb}^{-1}$ 

## CODEX-b

A Compact Detector for Exotics at LHCb: 10 m  $\times$  10 m  $\times$  10 m  $[\underline{1708.09395}]$ 

Extracted from [1810.03617]

## MoEDAL-MAPP1 & MAPP2

- MoEDAL' s Apparatus for Penetrating Particles
- A sub-detector of the MoEDAL experiment [Universe 5 (2019) 2, 47] near IP8 of the LHCb
- $\bullet$  MAPP1 (approved): 130 m^3, during LHC run 3, 30 fb^{-1},  $\sim 55$  m from the IP
- MAPP2: 430 m<sup>3</sup>, HL-LHC, 300 fb<sup>-1</sup>, the whole of the UGC8 gallery

## FASER & FASER2

• ForwArd Search ExpeRiment: [<u>1901.04468</u>] a cylindrical detector in very forward direction along beam axis

- FASER duing LHC run 3 (approved), and FASER2 during HL-LHC
- $L + L_d = 480$  m,  $L_d = 1.5/5$  m, R = 0.1/1 m, full  $\phi$  coverage  $\eta : [9.17/6.86, \infty]$ ,  $\mathcal{L} = 150/3000$  fb<sup>-1</sup>
