#### CP Violation in hadronic two-body charm-meson decays

#### Luiz VALE SILVA

In collaboration with Antonio Pich and Eleftheria Solomonidi (IFIC, UV – CSIC) based on 2305.11951 (PRD 108 (2023) 3, 036026), and upcoming work

Future Tau Charm Facilities, 16/01/2024 – Hefei, China

# Charm-flavour physics

- Flavour physics of the up-type: <u>complementary</u>, but less well known than down-type strange and bottom sectors
  - QCD @ intermediate regime  $M_{\kappa} \ll m_{c} \ll m_{b}$  [consolidated theoretical tools for the two extrema,  $\chi PT_{3}$  and HQET; slower behaviour of the 1/m<sub>c</sub> perturbative series]
  - EW sector largely uncharted; more effective GIM mechanism: potential to identify BSM

# Measurement of direct CP

Major discovery by LHCb in 2019:

$$\Delta A_{\rm CP} = A_{\rm CP}(K^-K^+) - A_{\rm CP}(\pi^-\pi^+) \neq 0$$

D° to K<sup>-</sup>K<sup>+</sup> asym.  $D^{\circ}$  to  $\pi^{-}\pi^{+}$  asym.

[I will neglect indirect CPV throughout this talk]

- Bounds in many other cases:  $\pi^+\pi^-$  and K<sup>+</sup>K<sup>-</sup> (individually),  $\pi^0\pi^0$ ,  $\pi^+\pi^0$ , K<sub>s</sub>K<sub>s</sub>, K<sup>+</sup>K<sub>s</sub>, etc. [LHCb '22] [LHCb, BABAR, Belle, ...]
- Much progress is expected in this decade: LHCb Upgrade I and Belle II; about 3-fold better sensitivity to CPV in  $\Delta A_{CP}$

Future exp. sensitivity to penguins

## SM description of direct CPN

Theory has to match experimental progress

- We need both strong-phase (= $\delta$ ) and weak-phase (= $\phi$ ) differences
- Strong-phases enhance A<sub>CP</sub>, but also make its description more challenging
- **HERE**: discussion of **non-perturbative QCD effects**, their extraction from data, and physical impact on direct CPV in the charm sector

[see also: Brod, Grossman, Kagan, Zupan '12; Li, Lu, Yu '12; Franco, Mishima, Silvestrini '12; Cheng, Chiang '12; Khodjamirian, Petrov '17; Soni '19; Schacht, Soni '21; Lenz, Piscopo, Rusov '23; etc., etc.]

#### Rescattering in weak decays

 Rescattering among stable on-shell particles produces a CP-even (strong) phase; elastic limit: Watson theorem

phase of the  $\pi$  FF = (phase-shift  $\pi\pi \to \pi\pi$ ) mod 180°, @ elastic region above  $\pi\pi$  threshold

- Separate strong and weak dynamics; final-state rescattering in transition amplitude encoded in process-independent  $\Omega$
- Relate dispersive and absorptive parts based on **analyticity** of the amplitudes (Mandelstam variables)

(dispersive)  

$$\operatorname{Re}[\Omega(s)] = \frac{1}{\pi} \int_{4M_{\pi}^2}^{\infty} \frac{\operatorname{Im}[\Omega(s')]}{s' - s} ds'$$

Dispersion Relation (DR) for  $\Omega$  entering the transition amplitude

#### **Omnes factor**

• Elastic limit, explicit solution of the integral equation:

- IR: phase-shift and Omnes factor embody the effects of rescattering in the amplitudes of weak decays
- UV: polynomial ambiguity (analytical properties of  $\Omega$  unchanged), requires some physical input [e.g., in K to  $\pi\pi$ , employ  $\chi PT_3$ ]

[Pallante, Pich '99 '00; Pallante, Pich, Scimemi '01; Gisbert, Pich '17]

Luiz VALE SILVA – Direct CPV in charm

#### Two-channel analysis of rescattering

 Inelastic case: set of integral equations (DRs) related by unitarity; no explicit solution known; DRs have to be solved numerically

[Moussallam '00; Descotes-Genon '03]

- Neglect the effect of further channels
- Experimental input for (ππ, KK) phaseshifts and inelasticity (ππ ↔ KK) in isospin=0 available [Garcia-Martin, Kaminski, Pelaez

Luiz VALE SILVA – Direct CPV in charm

[Garcia-Martin, Kaminski, Pelaez, Ruiz de Elvira, Yndurain '11; Pelaez, Rodas, Ruiz De Elvira '19; Pelaez, Rodas '20][Buettiker, Descotes-Genon, Moussallam '04]

$$R(s) = R(s_0) + \frac{s - s_0}{\pi} \int_{4M_\pi^2}^{\infty} ds' \frac{1}{s' - s} \frac{X(s')R(s')}{s' - s_0}$$

R: real part of amplitudes X: <u>2-by-2 rescattering matrix</u> [X =  $tan(\delta)$  in the elastic limit]

### Further physical inputs

- Subtraction constant of DRs taken from large-N<sub>c</sub>; improvement given by rescattering (sub-leading in large-N<sub>c</sub>)
- Decay constants and form factors (independent sub-leading large-N<sub>c</sub> effects)
- Large perturbative QCD effects  $\alpha_s(\mu)*log(\mu/M_w)$  are included in Wilson Coefficients (RGE improvement)

[Buras, Gerard, Rueckl '85; Bauer, Stech, Wirbel '86; Buras, Silvestrini '00; Mueller, Nierste, Schacht '15]

Isospin analysis: information from D<sup>+</sup> to π<sup>+</sup>π<sup>0</sup>, K<sup>+</sup>K<sub>s</sub> branching ratios into D<sup>0</sup> decays; phase-shifts of final states with isospin=1 and =2 undetermined
 Luiz VALE SILVA – Direct CPV in charm

# CP-even amplitudes and BRs

$$\begin{split} & \mathcal{W}\mathrm{Cs} \ , \ \mathrm{D}\mathrm{Cs} \ , \ \mathrm{FFs} \ , \ \mathrm{rescattering \ factors} \ , \ \mathrm{and} \ \mathrm{D}^+ \ \mathrm{BRs} \\ & \mathrm{isospin \ decomposition:} \ \ A^\pi_0 \ , \ A^\pi_2 \ , \ \ A^K_0 \ , \ A^K_{11} \ , \ A^K_{13} \\ & \mathcal{B}(D^0 \to \pi^+ \pi^-, \pi^0 \pi^0)_{theo} & \mathcal{B}(D^0 \to K^+ K^-, K_S K_S)_{theo} \end{split}$$

- **BR**<sub>theo</sub>~**BR**<sub>exp</sub> can be found; however, <u>large uncertainties are present</u>
- Inelasticity is the main source of uncertainties
- Use BRs to control uncs. of dispersive inputs: better prediction for ACP

- Phase-shifts of final states with isospin=2 and =1 adjusted
- Isospin=0: source of breaking of symmetry between pions and kaons, of size similar to  $f_{\kappa}/f_{\pi}$  & F^{DK}/F^{D\pi}
- Other sources of breaking: I=2 (from D<sup>+</sup> to  $\pi^+\pi^0$ ), I=1 (from D<sup>+</sup> to K<sup>+</sup>K<sub>S</sub>)
- Luiz VALE SILVA Direct CPV in charm

# Mechanisms of CPV

Isospin=0:

rescattering factors

$$\begin{pmatrix} A_0^{\pi} + i B_0^{\pi} \\ A_0^{K} + i B_0^{K} \end{pmatrix} = \Omega(M_D^2) \underbrace{\begin{pmatrix} \lambda_d T_{\pi\pi}^{CC} - \lambda_b T_{\pi\pi}^{P} \\ \lambda_s T_{KK}^{CC} - \lambda_b T_{KK}^{P} \end{pmatrix}}_{\text{CKM factors, WCs, DCs, FFs}}$$

similar expressions for I=2 (pions) and I=1 (kaons), which are treated elastically

- CPV from different interference terms between amplitudes
- I=0/I=0: possible due to rescattering; correlation in pions and kaons: CPV[ππ]+CPV[KK]=0
- I=0 interference with exotic states: I=2 (pions), I=1 (kaons)
- scalar+/-pseudoscalar structure: small WC, but enhanced

 $\frac{2 M_{\pi}^2}{(m_u + m_d) m_c}, \frac{2 M_K^2}{m_s m_c} \sim 5$ @  $\mu \sim 2 \text{ GeV}$ [cf. Li, Lu, Yu '12; Cheng, Chiang '12; Soni '19]

Luiz VALE SILVA – Direct CPV in charm

- Weak-phase: rephasing-invariant Jarlskog/ $|\lambda_d|^2$  from bottom & strange
- Small CPV: rescattering effects not large enough
- It seems difficult to explain the measured CPV based on this approach

Luiz VALE SILVA – Direct CPV in charm

# Summary & Conclusions

• Data-driven approach: isospin=0 rescattering effects through DRs; isospin=2 & isospin=1 rescattering effects from D<sup>+</sup> to  $\pi^+\pi^0$ , K<sup>+</sup>K<sub>s</sub> BRs

subtraction constants given by large- $N_c$ 

- Exp. values of  $\pi^{\scriptscriptstyle +}\pi^{\scriptscriptstyle -},\,\pi^{\scriptscriptstyle 0}\pi^{\scriptscriptstyle 0}$  and K^+K^-, K\_sK\_s BRs used to control uncertainties
- Predicted CP asymmetries are too small

### Outlook

- Constrain ΔA<sub>CP</sub> based on unitarity, CPT and DRs [Pich, Solomonidi, LVS, in progress]
- Test use of DRs in Cabibbo allowed and doubly Cabibbo suppressed modes [Camarasa Domene, LVS, in progress]
- Complementary signs of CPV: look into decay modes with higher multiplicity  $\rightarrow$  LHCb, Belle II, BESIII, STCF
- Apply DRs in the description of rare charm-meson decay modes [see Fajfer, Solomonidi, LVS, 2312.07501]

Many thanks!, *XièXie!* 

#### Fit of isospin amplitudes [not including LHCb '22]

isospin decomposition:  $A_0^{\pi}, B_0^{\pi}, A_2^{\pi}, A_0^{K}, B_0^{K}, A_{11}^{K}, B_{11}^{K}, A_{13}^{K}$ [Franco, Mishima, Silvestrini '12]

- Incorporate unitarity @ m<sub>p</sub> only
- Amplitudes satisfy relations involving phaseshifts and inelasticity, that can be implemented in the isospin fit

# Operator basis and CPV

- One effect of CPV comes from non-unitarity of the 2-by-2 CKM sub-matrix; CPodd contribution comes from loop topologies with insertions of current-current operators (light flavours in the loop, i.e., long-distance effect)
- WCs of penguin operators are tiny (aka GIM mechanism), but their contribution may be enhanced
- The quantity Q<sub>udcs</sub> is rephasing-invariant and has an imaginary part, namely, the Jarlskog

μ	$C_1$	$C_2$	$C_3$	$C_4$	$C_5$	$C_6$
$m_c$	1.22	-0.40	0.021	-0.055	0.0088	-0.060
2  GeV	1.18	-0.32	0.011	-0.031	0.0068	-0.032

[Buchalla, Buras, Lautenbacher '95]

$$\lambda_d \lambda_s^* = V_{ud} V_{cs} V_{us}^* V_{cd}^* = Q_{udcs}$$

#### **Implications of a Large Phase Shift**

 $\mathcal{A}_{I} \equiv \mathcal{A}_{I} e^{i\delta_{I}} = \text{Dis}(\mathcal{A}_{I}) + i \text{Abs}(\mathcal{A}_{I})$ 

Important  
difference with  
charm physics:  
analogous kaon  
process is elastic;  
moreover, in  
charm, e.g.:  

$$\arg(A_2^{\pi/A_0^{\pi}}) \sim \pm 90^{\circ}$$
  
**1** Unitarity:  $\delta_0(M_K) = (39.2 \pm 1.5)^{\circ} \rightarrow A_0 \approx 1.3 \times \text{Dis}(\mathcal{A}_0)$   
 $tan \delta_l = \frac{\text{Abs}(\mathcal{A}_l)}{\text{Dis}(\mathcal{A}_l)}$   
 $A_l = \text{Dis}(\mathcal{A}_l) \sqrt{1 + \tan^2 \delta_l}$   
**2** Analyticity:  $\Delta \text{Dis}(\mathcal{A}_l)[s] = \frac{1}{\pi} \int dt \frac{\text{Abs}(\mathcal{A}_l)[t]}{t-s-i\epsilon} + \text{subtractions}$ 

 $\rightarrow$  Large Abs  $(\mathcal{A}_0)$   $\rightarrow$  Large correction to Dis  $(\mathcal{A}_0)$
